Our budget limits how much we can spend on cameras and other computer-vision hardware. A lower-cost camera may reduce the overall project cost, but we are bound within the specs of the camera. If we choose to purchase a higher-end camera, it could improve the quality of the computer-vision system but would increase the project's overall cost. Along with a camera, we might need to make additional purchases to get it setup, costing us ~\$500, which is a significant expense for a self-led student project.

In terms of security constraints, depending on how the cameras for the dartboard connect to the computer, there could be eavesdropping. Particularly, if the cameras are connected wirelessly, via Bluetooth for instance, a bad actor could eaves drop on the data being sent to the computer from said cameras. However, a wired connection like USB-A or USB-C, could prevent this eavesdropping. Another possible security constraint for this project is where the application for the dartboard game will be hosted/run. If the application is a web app, it could be a target for bad actors to manipulate high score values, for example. A locally run application reduces the risk of such an attack.

Since our project is supposed to be for social events or inactive activity, if we fail to get the project up and running then it has no other practical use. Also, if we do not add any good features, it could not be a fun social project.
